We describe the calculation of the two-loop operator matrix elements for massive external fermions. These matrix elements are needed for the calculation of the  $O(\alpha^2)$  initial state radiative corrections to  $e^+e^-$  annihilation into a neutral virtual gauge boson, based on the renormalization group technique.

## 1. Introduction

The  $O(\alpha^2)$  initial state QED corrections to  $e^+e^-$  annihilation into a virtual photon or  $Z$ -boson were only calculated once in Ref. [1] in a standard Feynman diagram calculation. Due to the smallness of the ratios  $\xi = m^2/s'$ , with  $m$  the electron mass and  $s'$  the cms momentum squared of the virtual gauge boson, power corrections in  $\xi$  are negligible and only the logarithmic and constant terms in this parameter have to be maintained. The renormalization group equation, applied to this process, allows to derive all contributing terms in the on-mass-shell scheme. Our goal is to calculate all these terms and to check the result derived in [1] previously.

In this limit the differential scattering cross section is given in Mellin space by

$$\begin{aligned} \frac{d\sigma_{e^+e^-}}{ds'} &= \frac{1}{s} \sigma^{(0)}(s') \left\{ 1 + a_0 \left[ P_{ee}^{(0)} \cdot \mathbf{L} + \left( \tilde{\sigma}_{ee}^{(0)} + 2\Gamma_{ee}^{(0)} \right) \right] + a_0^2 \left\{ \left[ \frac{1}{2} P_{ee}^{(0)2} - \frac{\beta_0}{2} P_{ee}^{(0)} + \frac{1}{4} P_{e\gamma}^{(0)} \cdot P_{\gamma e}^{(0)} \right] \mathbf{L}^2 \right. \right. \\ &+ \left. \left[ P_{ee}^{(1)} + P_{ee}^{(0)} \left( \tilde{\sigma}_{ee}^{(0)} + 2\Gamma_{ee}^{(0)} \right) - \beta_0 \tilde{\sigma}_{ee}^{(0)} + P_{\gamma e}^{(0)} \tilde{\sigma}_{e\gamma}^{(0)} + \Gamma_{\gamma e}^{(0)} P_{e\gamma}^{(0)} \right] \mathbf{L} \right. \\ &\left. \left. + \left( 2\Gamma_{ee}^{(1)} + \tilde{\sigma}_{ee}^{(1)} \right) + 2\Gamma_{ee}^{(0)} \tilde{\sigma}_{ee}^{(0)} + 2\tilde{\sigma}_{e\gamma}^{(0)} \Gamma_{\gamma e}^{(0)} + \Gamma_{ee}^{(0)2} \right\} \right\}. \end{aligned} \quad (1.1)$$

Here the  $\Gamma$ 's denote the massive operator matrix elements, the  $\tilde{\sigma}$ 's are massless Wilson coefficients, and the  $P$ 's are splitting functions.  $\sigma^{(0)}(s)$  is the Born level scattering cross section in terms of the invariant mass  $s$  of the initial  $e^+e^-$  pair and  $\mathbf{L} = \ln(s'/m^2)$ . It is convenient to represent the differential scattering cross section in terms of three contributions, the flavor non-singlet terms with a single fermion line (I), those with a closed fermion line (II), and the pure-singlet terms (III).<sup>1</sup> These contributions are :

$$\begin{aligned} \frac{d\sigma_{e^+e^-}^{\text{I}}}{ds'} &= \frac{1}{s} \sigma^{(0)}(s') \left\{ 1 + a_0 \left[ P_{ee}^{(0)} \cdot \mathbf{L} + \left( \tilde{\sigma}_{ee}^{(0)} + 2\Gamma_{ee}^{(0)} \right) \right] + a_0^2 \left\{ \frac{1}{2} P_{ee}^{(0)2} \mathbf{L}^2 \right. \right. \\ &\left. \left. + \left[ P_{ee}^{(1),\text{I}} + P_{ee}^{(0)} \left( \tilde{\sigma}_{ee}^{(0)} + 2\Gamma_{ee}^{(0)} \right) \right] \mathbf{L} + \left( 2\Gamma_{ee}^{(1),\text{I}} + \tilde{\sigma}_{ee}^{(1),\text{I}} \right) + 2\Gamma_{ee}^{(0)} \tilde{\sigma}_{ee}^{(0)} + \Gamma_{ee}^{(0)2} \right\} \right\} \end{aligned} \quad (1.2)$$

$$\frac{d\sigma_{e^+e^-}^{\text{II}}}{ds'} = \frac{1}{s} \sigma^{(0)}(s') a_0^2 \left\{ -\frac{\beta_0}{2} P_{ee}^{(0)} \mathbf{L}^2 + \left[ P_{ee}^{(1),\text{II}} - \beta_0 \tilde{\sigma}_{ee}^{(0)} \right] \mathbf{L} + \left( 2\Gamma_{ee}^{(1),\text{II}} + \tilde{\sigma}_{ee}^{(1),\text{II}} \right) \right\} \quad (1.3)$$

$$\begin{aligned} \frac{d\sigma_{e^+e^-}^{\text{III}}}{ds'} &= \frac{1}{s} \sigma^{(0)}(s') a_0^2 \left\{ \frac{1}{4} P_{e\gamma}^{(0)} \cdot P_{\gamma e}^{(0)} \mathbf{L}^2 + \left[ P_{ee}^{(1),\text{III}} + P_{\gamma e}^{(0)} \tilde{\sigma}_{e\gamma}^{(0)} + \Gamma_{\gamma e}^{(0)} P_{e\gamma}^{(0)} \right] \mathbf{L} \right. \\ &\left. + \left( 2\Gamma_{ee}^{(1),\text{III}} + \tilde{\sigma}_{ee}^{(1),\text{III}} \right) + 2\tilde{\sigma}_{e\gamma}^{(0)} \Gamma_{\gamma e}^{(0)} \right\}. \end{aligned} \quad (1.4)$$

The massless Wilson coefficients are known in the literature in the  $\overline{\text{MS}}$  scheme for the Drell-Yan process [2, 3]. The leading and next-to-leading order splitting functions  $P_{ij}^{(0)}$  and  $P_{ij}^{(1)}$  are well-known from QCD. The only missing piece we need to calculate are the massive fermionic operator matrix elements  $\Gamma_{ij}^{(k)}$  to  $O(\alpha^2)$ . In the following sections, we describe this calculation.

<sup>1</sup>In Ref. [1] four contributions were considered dividing those to I into two pieces according to the genuine  $2 \rightarrow 3$  particle scattering cross sections.

## 2. Calculation techniques

To obtain  $\Gamma_{ee}^{(1),I-III}$  we calculate the diagrams in figure 1 (and the corresponding self-energy diagrams) using the rules shown in figure 2 for an external massive fermion (anti-fermion)<sup>2</sup> for general integer values of the Mellin-moment  $n$  in the form

$$\tilde{\Gamma}_{ee}^{(1)}(n) = \int_0^1 dz z^{n-1} \Gamma_{ee}^{(1)}(z). \quad (2.1)$$

In this way we can separate the splitting function  $P_A(x)$  [4] from the remainder non-singlet splitting function in the single pole term  $1/\varepsilon$  and in the constant part of the operator matrix element.

Since we consider the radiative corrections to the time-like process<sup>3</sup>  $e^+e^- \rightarrow Z_0$  up to two-loop order for both initial states, the particle nature has to be conserved, i.e. only  $e^- \rightarrow e^-$  and  $e^+ \rightarrow e^+$  transitions contribute, which requires a corresponding projection in  $\Gamma_{ee}^{(1)}(x)$ .

All of the diagrams can be written as a linear combination of integrals of the following type:

$$A_{v_1, v_2, v_3, v_4, v_5}^{a,b} = \int \frac{d^D k_1}{(4\pi)^D} \frac{d^D k_2}{(4\pi)^D} \frac{(\Delta \cdot k_1)^a (\Delta \cdot k_2)^b}{D_1^{v_1} D_2^{v_2} D_3^{v_3} D_4^{v_4} D_5^{v_5}} \quad (2.2)$$

$$B_{v_1, v_2, v_3, v_4, v_5}^{a,b} = \int \frac{d^D k_1}{(4\pi)^D} \frac{d^D k_2}{(4\pi)^D} \frac{k_2 \cdot p (\Delta \cdot k_1)^a (\Delta \cdot k_2)^b}{D_1^{v_1} D_2^{v_2} D_3^{v_3} D_4^{v_4} D_5^{v_5}} \quad (2.3)$$

$$F_{v_1, v_2, v_3, v_4, v_5}^{a,b} = \int \frac{d^D k_1}{(4\pi)^D} \frac{d^D k_2}{(4\pi)^D} \frac{(\Delta \cdot k_1)^a (\Delta \cdot k_2)^b}{D_1^{v_1} D_2^{v_2} D_3^{v_3} D_4^{v_4} D_5^{v_5}} \sum_{j=0}^{n-1} (\Delta \cdot p)^j (\Delta \cdot k_1)^{n-1-j} \quad (2.4)$$

$$G_{v_1, v_2, v_3, v_4, v_5}^{a,b} = \int \frac{d^D k_1}{(4\pi)^D} \frac{d^D k_2}{(4\pi)^D} \frac{(\Delta \cdot k_1)^a (\Delta \cdot k_2)^b}{D_1^{v_1} D_2^{v_2} D_3^{v_3} D_4^{v_4} D_5^{v_5}} \sum_{j=0}^{n-1} (\Delta \cdot k_1)^j (\Delta \cdot k_2)^{n-1-j} \quad (2.5)$$

and a couple more of integrals associated with the diagrams that have two photons coming out of the vertex. Here  $D_1 = k_1^2 - m^2$ ,  $D_2 = k_2^2 - m^2$ ,  $D_3 = (k_1 - p)^2$ ,  $D_4 = (k_1 - k_2)^2$  and  $D_5 = (k_2 - k_1 + p)^2 - m^2$ , with  $p$  the momentum of the electron. For example, the cross-box diagram appearing in figure 1 can be written in terms of these integrals as follows

$$\begin{aligned} & (D-4)(D-2) \left[ 2A_{12001}^{0,n+1} - 2A_{02110}^{0,n+1} - A_{01111}^{1,n} + A_{11011}^{1,n} - A_{11101}^{1,n} + A_{11110}^{1,n} + (\Delta \cdot p)A_{01111}^{0,n} \right] \\ & + (D-8)(D-2) \left[ A_{01111}^{0,n+1} - A_{11011}^{0,n+1} - (\Delta \cdot p)A_{10111}^{0,n} + (\Delta \cdot p)A_{11101}^{0,n} \right] + 32m^4 A_{12111}^{0,n+1} \\ & + 16(D-3)m^2 \left[ A_{12011}^{0,n+1} + A_{12101}^{0,n+1} \right] + 4(D-4)m^2 \left[ (\Delta \cdot p)A_{11111}^{0,n} - A_{11111}^{0,n+1} \right] + 8m^2 A_{02111}^{0,n+1} \\ & + 8m^2 A_{12110}^{0,n+1} + 4(D-2) \left[ A_{11101}^{0,n+1} - A_{11110}^{0,n+1} - 2B_{12011}^{0,n+1} - 2B_{12101}^{0,n+1} + (\Delta \cdot p)A_{11011}^{0,n} \right]. \quad (2.6) \end{aligned}$$

These integrals can be calculated in various ways. In case of external gluon lines the  $O(\alpha_s^2)$  integrals appearing in the massive operator matrix elements [6] can be calculated using Mellin-Barnes techniques and representations in terms of generalized hypergeometric functions without using the integration-by-parts technique. Working in Mellin space one may solve difference equations for harmonic sums [7], cf. [8], which leads to ab initio compact expressions. In the present

<sup>2</sup>We recalculated the LO OME's and corrected typographical errors in [1].

<sup>3</sup>In space-like processes as deeply inelastic scattering  $e^- \rightarrow e^+$  transitions do even occur in  $O(\alpha^2 L^2)$ , cf. [5].

**Figure 1:** Two-loop diagrams contributing to the massive operator matrix elements. The antisymmetric diagrams count twice.

**Figure 2:** Feynman rules.

case, we follow the more traditional way of calculation, which was also used in [9]. The massive 5-propagator integrals are reduced to 4-propagator integrals using the integration-by-parts technique [10]. For example, one of the most complicated integrals coming from the cross-box diagram, namely  $A_{12111}^{0,n}$ , can be decomposed as follows

$$A_{12111}^{0,n} = \frac{1}{\varepsilon} \left[ -A_{12210}^{0,n} - A_{02211}^{0,n} - A_{12102}^{0,n} - A_{22101}^{0,n} \right. \\ \left. + \frac{1}{1+\varepsilon} \left( -2A_{31101}^{0,n} + 2A_{30111}^{0,n} - A_{21210}^{0,n} + 2A_{20211}^{0,n} - A_{21102}^{0,n} \right. \right. \\ \left. \left. - A_{21201}^{0,n} - 2A_{11310}^{0,n} - 2A_{10311}^{0,n} - A_{01311}^{0,n} - A_{11202}^{0,n} \right) \right]. \quad (2.7)$$

The 4-propagator integrals obey representations in terms of up to three Feynman parameter integrals over the unit cube. In course of the calculation we arrange the structure of the Feynman parameter integrals such that they have the form

$$F(\varepsilon, N) = \int_0^1 dx x^N \int_0^1 dy \int_0^1 dz f(x, y, z; \varepsilon). \quad (2.8)$$

The arts of integration consist now in performing the numerous integrals (2.8) in Feynman parameter space. This partly requires Mellin-Barnes representations, repeated conformal mapping of integration variables, the use of parameter mappings for hypergeometric integrals, and extended regularization. Numerous integrals of (Nielsen) polylogarithms [11] normally of complicated arguments have to be performed. It turns out that the final results can be expressed in terms of Nielsen integrals, partly weighted by denominators  $1/x, 1/(1-x)^k, 1/(1+x)^l$ ,  $k \leq 3, l \leq 2$ . This structure

is expected similar to that occurring in case of a wide variety of other 2-loop quantities [12]. For example, the integral mentioned above gives

$$\begin{aligned}
A_{12111}^{0,n} = \int_0^1 dx x^n \left\{ \frac{2}{3} \text{Li}_2(1-x) + \frac{1}{3} \ln^2(x) + \frac{2}{3(1-x)} \ln(x) + \frac{2}{3} \zeta_2 \right. \\
- \frac{1}{3} (1-x)^{-3-2\epsilon} \ln^2(x) - \frac{2}{3} (1-x)^{-2-2\epsilon} \ln(x) \\
+ \frac{2}{3} (1-x)^{-1-2\epsilon} + \epsilon (1-x)^{-1-2\epsilon} (2\zeta_2 - 1) \\
+ (-1)^n \left[ \frac{4}{3} \text{Li}_2(-x) - \frac{2}{3} \left( 1 - \frac{2}{(1+x)^3} \right) \text{Li}_2(1-x) \right. \\
- \left( 1 - \frac{1}{(1+x)^3} \right) \ln^2(x) + \frac{4}{3} \ln(x) \ln(1+x) \\
+ \frac{2}{3(1+x)} \left( \frac{2}{(1+x)^2} - \frac{1}{(1+x)} - 1 \right) \ln(x) \\
\left. \left. - \frac{2}{3(1+x)} + \frac{4}{3(1+x)^2} + \frac{2}{3} \zeta_2 \right] \right\}. \tag{2.9}
\end{aligned}$$

Detailed checks of the analytic calculations were performed using numerical integrations at high precision with MAPLE for fixed moments and individual integrals whenever possible. Mellin-Barnes integrals were performed for comparison in a series of fixed moments using the code MB [13]. We also compared to a few low (0th–2nd) moments for some of the scalar integrals to the results obtained using tarcer [14] based on the algorithm [15].

We compared the results of our calculation to that in [1] in the logarithmic orders and agree after correcting a series of typographical errors in some functions there, decomposing the scattering cross section according to the renormalization group. The final result including the constant term will be published soon.

### 3. Conclusion

Since the scale  $m^2/s' \ll 1$  the QED initial state radiative corrections to  $e^+e^- \rightarrow Z^*/\gamma^*$  to  $O(\alpha^2)$  can be calculated neglecting the power corrections. Alternatively to a direct calculation one may use the renormalization group to arrange the calculation in terms of convolutions of splitting functions, massless Wilson coefficients and process-independent massive operator matrix elements. The latter quantities with outer massive fermion lines form the essential part of the present calculation. We used the integration-by-parts technique to reduce the integrals to 4-propagator integrals, which lead to Mellin moments in terms of triple Feynman parameter integrals. The differential scattering cross section can be obtained as assembly of the massive operator matrix elements, massless Wilson coefficients for the Drell-Yan process and the splitting functions to two-loop orders.
